

LECTURE - IV
- PROCESSES & THREADS

Tevfik Koşar

Louisiana State University
January 25th, 2007

Roadmap

- Processes
 - Process Termination
 - Producer-Consumer Problem
 - Inter-process Communication
- Threads
 - Threads vs Processes
 - Multi-threading Models
 - Threading Issues

2

Process Termination

- Process executes last statement and asks the operating system to delete it (**exit**)
 - Output data from child to parent (via **wait**)
 - Process' resources are deallocated by operating system
- Parent may terminate execution of children processes (**abort**)
 - Child has exceeded allocated resources
 - Task assigned to child is no longer required
 - If parent is exiting
 - Some operating system do not allow child to continue if its parent terminates
 - All children terminated - **cascading termination**

3

Cooperating Processes

- **Independent** process cannot affect or be affected by the execution of another process
- **Cooperating** process can affect or be affected by the execution of another process
- Advantages of process cooperation
 - Information sharing
 - Computation speed-up
 - Modularity
 - Convenience

4

Producer-Consumer Problem

- Paradigm for cooperating processes, *producer* process produces information that is consumed by a *consumer* process
 - **unbounded-buffer** places no practical limit on the size of the buffer
 - **bounded-buffer** assumes that there is a fixed buffer size

5

Bounded-Buffer - Shared-Memory Solution

- Shared data

```
#define BUFFER_SIZE 10
typedef struct {
    . . .
} item;

item buffer[BUFFER_SIZE];
int in = 0;
int out = 0;
```
- Solution is correct, but can only use BUFFER_SIZE-1 elements

6

Bounded-Buffer - Insert() Method

```
while (true) {
    /* Produce an item */
    while (((in = (in + 1) % BUFFER SIZE
count) == out)
        ; /* do nothing -- no free buffers */
    buffer[in] = item;
    in = (in + 1) % BUFFER SIZE;
}
```

7

Bounded Buffer - Remove() Method

```
while (true) {
    while (in == out)
        ; // do nothing -- nothing to
        consume

    // remove an item from the buffer
    item = buffer[out];
    out = (out + 1) % BUFFER SIZE;
    return item;
}
```

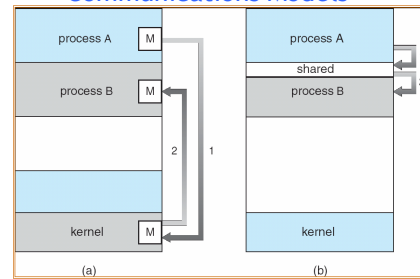

8

Interprocess Communication (IPC)

- Mechanism for processes to communicate and to synchronize their actions
- **Shared Memory:** by using the same address space and shared variables
- **Message Passing:** processes communicate with each other without resorting to shared variables
- Message Passing facility provides two operations:
 - `send(message)` - message size fixed or variable
 - `receive(message)`
- If *P* and *Q* wish to communicate, they need to:
 - establish a *communication link* between them
 - exchange messages via `send/receive`

9

Communications Models

a) Message Passing

b) Shared Memory

10

Message Passing - direct communication

- Processes must name each other explicitly:
 - `send(P, message)` - send a message to process P
 - `receive(Q, message)` - receive a message from process Q
- Properties of communication link
 - Links are established automatically
 - A link is associated with exactly one pair of communicating processes
 - Between each pair there exists exactly one link
 - The link may be unidirectional, but is usually bi-directional
- Symmetrical vs Asymmetrical direct communication
 - `send(P, message)` - send a message to process P
 - `receive(id, message)` - receive a message from any process
- Disadvantage of both: limited modularity, hardcoded

11

Message Passing - indirect communication

- Messages are directed and received from mailboxes (also referred to as ports)
 - Each mailbox has a unique id
 - Processes can communicate only if they share a mailbox
- Primitives are defined as:
 - `send(A, message)` - send a message to mailbox A
 - `receive(A, message)` - receive a message from mailbox A

12

Indirect Communication (cont.)

- Operations
 - create a new mailbox
 - send and receive messages through mailbox
 - destroy a mailbox
- Properties of communication link
 - Link established only if processes share a common mailbox
 - A link may be associated with many processes
 - Each pair of processes may share several communication links
 - Link may be unidirectional or bi-directional

13

Indirect Communication (cont.)

- Mailbox sharing
 - P_1 , P_2 , and P_3 share mailbox A
 - P_1 sends; P_2 and P_3 receive
 - Who gets the message?
- Solutions
 - Allow a link to be associated with at most two processes
 - Allow only one process at a time to execute a receive operation
 - Allow the system to select arbitrarily the receiver. Sender is notified who the receiver was.

14

Synchronization

- Message passing may be either blocking or non-blocking
- **Blocking** is considered **synchronous**
 - **Blocking send** has the sender block until the message is received
 - **Blocking receive** has the receiver block until a message is available
- **Non-blocking** is considered **asynchronous**
 - **Non-blocking send** has the sender send the message and continue
 - **Non-blocking receive** has the receiver receive a valid message or null

15

Buffering

- Queue of messages attached to the link; implemented in one of three ways
 1. Zero capacity - 0 messages
Sender must wait for receiver (rendezvous)
 2. Bounded capacity - finite length of n messages
Sender must wait if link full
 3. Unbounded capacity - infinite length
Sender never waits

16

THREADS

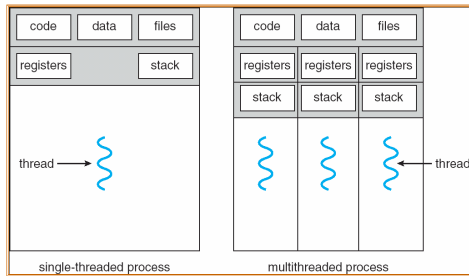

17

Motivation

- In certain cases, a single application may need to run several tasks at the same time
 - Create a new process for each task
 - Time consuming
 - Use a single process with multiple threads

18

Single and Multithreaded Processes

19

Multi-process model

Process Spawning:

- Process creation involves the following four main actions:
- setting up the process control block,
 - allocation of an address space and
 - loading the program into the allocated address space and
 - passing on the process control block to the scheduler

20

Multi-thread model

Thread Spawning:

- Threads are created *within and belonging to* processes
- All the threads created within one process share the resources of the process including the address space
- Scheduling is performed on a per-thread basis.
- The thread model is a *finer grain scheduling model* than the process model
- Threads have a similar *lifecycle* as the processes and will be managed mainly in the same way as processes are

21

Threads vs Processes

- Heavyweight Process = Process
- Lightweight Process = Thread

Advantages (Thread vs. Process):

- Much quicker to create a thread than a process
- Much quicker to switch between threads than to switch between processes
- Threads share data easily

Disadvantages (Thread vs. Process):

- Processes are more flexible
 - They don't have to run on the same processor
- No security between threads: One thread can stomp on another thread's data
- For threads which are supported by user thread package instead of the kernel:
 - If one thread blocks, all threads in task block.

22

Different Multi-threading Models

- Many-to-One
- One-to-One
- Many-to-Many

23

Many-to-One Model

- Several user-level threads mapped to single kernel thread
- Thread management in user space → efficient
- If a thread blocks, entire process blocks
- One thread can access the kernel at a time → limits parallelism
- Examples:
 - Solaris Green Threads
 - GNU Portable Threads

24

One-to-One Model

- Each user-level thread maps to a kernel thread
- A blocking thread does not block other threads
- Multiple threads can access kernel concurrently → increased parallelism
- Drawback: Creating a user level thread requires creating a kernel level thread → increased overhead and limited number of threads
- Examples: Windows NT/XP/2000, Linux, Solaris 9 and later

25

Many-to-Many Model

- Allows many user level threads to be mapped to a smaller number of kernel threads
- Allows the operating system to create a sufficient number of kernel threads
- Increased parallelism as well as efficiency
- Solaris prior to version 9
- Windows NT/2000 with the ThreadFiber package

26

Two-level Model

- Similar to M:M, except that it allows a user thread to be bound to kernel thread
- Examples: IRIX, HP-UX, Tru64 UNIX, Solaris 8 and earlier

27

Threading Issues

- Semantics of `fork()` and `exec()` system calls
- Thread cancellation
- Signal handling
- Thread pools
- Thread specific data

28

Semantics of `fork()` and `exec()`

- Semantics of `fork()` and `exec()` system calls change in a multithreaded program
 - Eg. if one thread in a multithreaded program calls `fork()`
 - Should the new process duplicate all threads?
 - Or should it be single-threaded?
 - Some UNIX systems implement two versions of `fork()`
 - If a thread executes `exec()` system call
 - Entire process will be replaced, including all threads

29

Thread Cancellation

- Terminating a thread before it has finished
 - If one thread finishes the searching a database, others may be terminated
 - If user presses a button on a web browser, web page can be stopped from loading further
- Two approaches to cancel the target thread
 - **Asynchronous cancellation** terminates the target thread immediately
 - **Deferred cancellation** allows the target thread to periodically check if it should be cancelled
 - More controlled and safe

30

Signal Handling

- Signals are used in UNIX systems to notify a process that a particular event has occurred
- All signals follow this pattern:
 1. Signal is generated by particular event
 2. Signal is delivered to a process
 3. Once delivered, a signal must be handled
- In **multithreaded systems**, there are 4 options:
 - Deliver the signal to the thread to which the signal applies
 - Deliver the signal to every thread in the process
 - Deliver the signal to certain threads in the process
 - Assign a specific thread to receive all signals for the process

31

Thread Pools

- Threads come with some overhead as well
- Unlimited threads can exhaust system resources, such as CPU or memory
- Create a number of threads at process startup) and put them in a pool, where they await work
- When a server receives a request, it awakens a thread from this pool
- Advantages:
 - Usually faster to service a request with an existing thread than create a new thread
 - Allows the number of threads in the application(s) to be bound to the size of the pool
- Number of threads in the pool can be setup according to:
 - Number of CPUs, memory, expected number of concurrent requests

32

Thread Specific Data

- Threads belonging to the same process share the data of the process
- In some cases, each thread needs to have its own copy of data → **thread specific**
- Useful when you do not have control over the thread creation process (i.e., when using a thread pool)

33

Any Questions?

34

Reading Assignment

- Read chapter 4 from Silberschatz.

35

Acknowledgements

- “Operating Systems Concepts” book and supplementary material by Silberschatz, Galvin and Gagne.

36
