CSC 4103 - Operating Systems Fall 2009

LECTURE - V
CPU SCHEDULING - I

Tevfik Koşar

Louisiana State University September 10th, 2009

## Roadmap

- CPU Scheduling
  - Basic Concepts
  - Scheduling Criteria & Metrics
  - Different Scheduling Algorithms
    - FCFS
    - SJF
    - Priority
    - RR

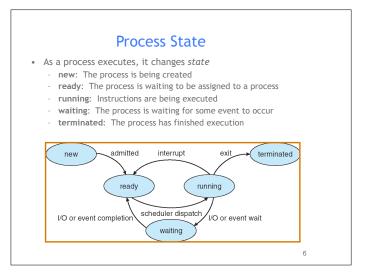

2

# **Basic Concepts**

- Multiprogramming is needed for efficient CPU utilization
- CPU Scheduling: deciding which processes to execute when
- Process execution begins with a CPU burst, followed by an I/O burst
- CPU-I/O Burst Cycle Process execution consists of a *cycle* of CPU execution and I/O wait

3

# Alternating Sequence of CPU And I/O Bursts | load store add store read from file | I/O burst | | wait for I/O | I/O burst | | wait

#### **CPU** Scheduler

- Selects from among the processes in memory that are ready to execute, and allocates the CPU to one of them
  - → short-term scheduler
- CPU scheduling decisions may take place when a process:
- 1. Switches from running to waiting state
- 2. Switches from running to ready state
- 3. Switches from waiting to ready
- 4. Terminates
- Scheduling under 1 and 4 is nonpreemptive/cooperative
  - Once a process gets the CPU, keeps it until termination/switching to waiting state/release of the CPU
- All other scheduling is *preemptive* 
  - Most OS use this
  - Cost associated with access to shared data
  - i.e. time quota expires

7

#### Dispatcher

- Dispatcher module gives control of the CPU to the process selected by the short-term scheduler;
   Its function involves:
  - switching context
  - switching to user mode
  - jumping to the proper location in the user program to restart that program
- Dispatch latency time it takes for the dispatcher to stop one process and start another running

8

# Scheduling Criteria

- CPU utilization keep the CPU as busy as possible --> maximize
- Throughput # of processes that complete their execution per time unit -->maximize
- Turnaround time amount of time passed to finish execution of a particular process --> minimize
  - i.e. execution time + waiting time
- Waiting time total amount of time a process has been waiting in the ready queue --->minimize
- Response time amount of time it takes from when a request was submitted until the first response is produced, not output (for time-sharing environment) -->minimize

9

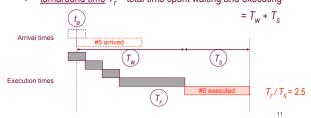

#### **Optimization Criteria**

- Maximize CPU utilization
- · Maximize throughput
- · Minimize turnaround time
- · Minimize waiting time
- Minimize response time

10

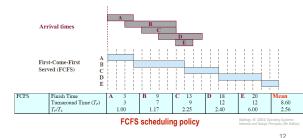

#### **Scheduling Metrics**

- Scheduling metrics
  - $\checkmark$  arrival time  $t_a$  = time the process became "Ready" (again)
  - ✓ wait time  $T_w$  = time spent waiting for the CPU
  - ✓ service time  $T_s$  = time spent executing in the CPU
  - $\checkmark$  turnaround time  $T_r$  = total time spent waiting and executing

#### First-Come, First-Served (FCFS) Scheduling

- ✓ processes are assigned the CPU in the order they request it
- ✓ when the running process blocks, the first "Ready" is run next
- ✓ when a process gets "Ready", it is put at the end of the queue

# FCFS Scheduling - Example

 $\begin{array}{ccc} \underline{Process} & \underline{Burst\ Time} \\ P_1 & 24 \\ P_2 & 3 \\ P_3 & 3 \end{array}$ 

• Suppose that the processes arrive in the order:  $P_1$  ,  $P_2$  ,  $P_3$ 

The Gantt Chart for the schedule is:

P <sub>1</sub>	F	2	$P_3$
0	24	27	30

• Waiting time for  $P_1 = 0$ ;  $P_2 = 24$ ;  $P_3 = 27$ 

• Average waiting time: (0 + 24 + 27)/3 = 17

10

# FCFS Scheduling - Example

Suppose that the processes arrive in the order

$$P_2$$
,  $P_3$ ,  $P_1$ 

• The Gantt chart for the schedule is:

• Waiting time for  $P_1 = 6$ ;  $P_2 = 0$ .  $P_3 = 3$ 

• Average waiting time: (6 + 0 + 3)/3 = 3

• Much better than previous case

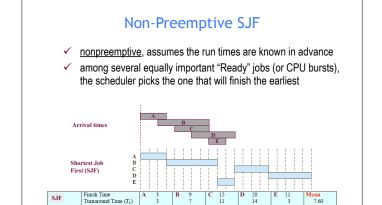

Convoy effect short process behind long process

14

#### Shortest-Job-First (SJF) Scheduling

- Associate with each process the length of its next CPU burst. Use these lengths to schedule the process with the shortest time
- Two schemes:
  - nonpreemptive once CPU given to the process it cannot be preempted until completes its CPU burst
  - preemptive if a new process arrives with CPU burst length less than remaining time of current executing process, preempt.
     -->This scheme is know as the Shortest-Remaining-Time-First (SRTF)
- SJF is optimal gives minimum average waiting time for a given set of processes

15

SJF scheduling policy

# Non-Preemptive SJF - Example

ProcessArrival TimeBurst Time $P_1$ 0.07 $P_2$ 2.04 $P_3$ 4.01 $P_4$ 5.04

• SJF (non-preemptive) Gantt Chart

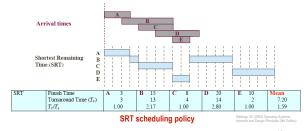

• Average waiting time = (0 + 6 + 3 + 7)/4 = 4

Preemptive SJF (SRT)

Shortest Remaining Time (SRT)

- ✓ preemptive version of SJF, also assumes known run time
- ✓ choose the process whose <u>remaining</u> run time is shortest
- ✓ allows new short jobs to get good service

18

# **Example of Preemptive SJF**

Process	Arrival Time	Burst Time
$P_1$	0.0	7
$P_2$	2.0	4
$P_3$	4.0	1
$P_4$	5.0	4

• SJF (preemptive) Gantt Chart

19

#### **Priority Scheduling**

- A priority number (integer) is associated with each process
- The CPU is allocated to the process with the highest priority (smallest integer = highest priority)
  - Preemntive
  - nonpreemptive
- SJF is a priority scheduling where priority is the predicted next CPU burst time
- Problem = Starvation low priority processes may never execute
- Solution = Aging as time progresses increase the priority of the process

20

# **Example of Priority**

	<b>Process</b>	<u>Arrival Time</u>	Burst Time	<b>Priority</b>
_	$P_1$	0.0	7	2
	$P_2$	2.0	4	1
	$P_3$	4.0	1	4
	$P_{\scriptscriptstyle A}$	5.0	4	3

- Priority (non-preemptive)
  - P1 --> P2 --> P4 --> P3
- Priority (preemptive)
  - ?

21

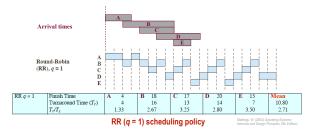

#### Round Robin (RR)

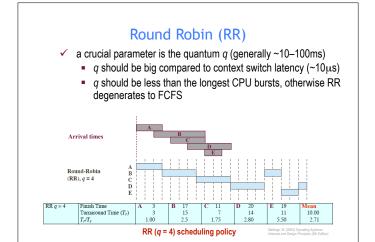

- Each process gets a small unit of CPU time (time quantum), usually 10-100 milliseconds.
   After this time has elapsed, the process is preempted and added to the end of the ready queue.
- If there are n processes in the ready queue and the time quantum is q, then each process gets 1/n of the CPU time in chunks of at most q time units at once. No process waits more than (n-1)q time units.
- Performance
  - $q \text{ large} \Rightarrow \text{FIFO}$

22

# Round Robin (RR)

- $\checkmark$  preemptive FCFS, based on a timeout interval, the **quantum** q
- the running process is interrupted by the clock and put last in a FIFO "Ready" queue; then, the first "Ready" process is run instead

# Example of RR with Time Quantum = 20

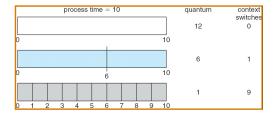

<u>Process</u>	<b>Burst Time</b>
$P_1$	53
$P_2$	17
$P_3$	68
$P_4$	24

• For q=20, the Gantt chart is:

	P <sub>1</sub>	P <sub>2</sub>	P <sub>3</sub>	P <sub>4</sub>	P <sub>1</sub>	P <sub>3</sub>	P <sub>4</sub>	P <sub>1</sub>	P <sub>3</sub>	P <sub>3</sub>	
C	) 2	0 3	7 5	7 7	77 9	7 11	7 1	21 13	34 1	54 16	32

 Typically, higher average turnaround than SJF, but better response

#### Time Quantum and Context Switch Time

26

#### Turnaround Time Varies With The Time Quantum

27

#### **Exercise**

Process ID	Arrival Time	Priority	Burst Time
A	0	3	20
В	5	1	15
С	10	2	10
D	15	4	5

- Draw gantt charts, find average turnaround and waiting times for above processes, considering:
- 1) First Come First Served Scheduling
- 2) Shortest Job First Scheduling (non-preemptive)
- 3) Shortest Job First Scheduling (preemptive)
- 4) Round-Robin Scheduling
- 5) Priority Scheduling (non-preemptive)
- 6) Priority Scheduling (preemptive)

28

#### **Summary**

- CPU Scheduling
  - Basic Concepts
  - Scheduling Criteria & Metrics
  - Different Scheduling Algorithms
    - FCFS
    - SJF
    - Priority
    - RR
