Deadlock Detection

- Allow system to enter deadlock state
- Detection algorithm
- Recovery scheme

2

Single Instance of Each Resource Type

- Maintain *wait-for* graph
 - Nodes are processes.
 - $P_i \rightarrow P_j$ if P_i is waiting for P_j .

Resource-Allocation Graph Corresponding wait-for graph

3

Single Instance of Each Resource Type

- Periodically invoke an algorithm that searches for a cycle in the graph.
- An algorithm to detect a cycle in a graph requires an order of n^2 operations, where n is the number of vertices in the graph.
- Only good for single-instance resource allocation systems.

4

Several Instances of a Resource Type

- *Available*: A vector of length m indicates the number of available resources of each type.
- *Allocation*: An $n \times m$ matrix defines the number of resources of each type currently allocated to each process.
- *Request*: An $n \times m$ matrix indicates the current request of each process. If $Request[i, j] = k$, then process P_i is requesting k more instances of resource type R_j .

5

Detection Algorithm

1. Let *Work* and *Finish* be vectors of length m and n , respectively Initialize:
 - (a) *Work* = *Available*
 - (b) For $i = 0, 2, \dots, n-1$, if $Allocation_i \neq 0$, then *Finish*[i] = false; otherwise, *Finish*[i] = true.
2. Find an index i such that both:
 - (a) *Finish*[i] == false
 - (b) $Request_i \leq Work$

If no such i exists, go to step 4.

6

Detection Algorithm (Cont.)

3. $Work = Work + Allocation_i$
 $Finish[i] = true$
 go to step 2.
4. If $Finish[i] == false$, for some i , $0 \leq i \leq n-1$, then the system is in deadlock state. Moreover, if $Finish[i] == false$, then P_i is deadlocked.

Algorithm requires an order of $O(m \times n^2)$ operations to detect whether the system is in deadlocked state.

7

Example of Detection Algorithm

- Five processes P_0 through P_4 ; three resource types A (7 instances), B (2 instances), and C (6 instances).
- Snapshot at time T_0 :

| | <u>Allocation</u> | | | <u>Request</u> | | | <u>Available</u> | | |
|-------|-------------------|---|---|----------------|---|---|------------------|---|---|
| | A | B | C | A | B | C | A | B | C |
| P_0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| P_1 | 2 | 0 | 0 | 2 | 0 | 2 | | | |
| P_2 | 3 | 0 | 3 | 0 | 0 | 0 | | | |
| P_3 | 2 | 1 | 1 | 1 | 0 | 0 | | | |
| P_4 | 0 | 0 | 2 | 0 | 0 | 2 | | | |

- Sequence $\langle P_0, P_2, P_3, P_1, P_4 \rangle$ will result in $Finish[i] = true$ for all i .

8

Example (Cont.)

- P_2 requests an additional instance of type C.

| | <u>Request</u> | | |
|-------|----------------|---|---|
| | A | B | C |
| P_0 | 0 | 0 | 0 |
| P_1 | 2 | 0 | 1 |
| P_2 | 0 | 0 | 1 |
| P_3 | 1 | 0 | 0 |
| P_4 | 0 | 0 | 2 |

- State of system?
 - Can reclaim resources held by process P_0 , but insufficient resources to fulfill other processes' requests.
 - Deadlock exists, consisting of processes P_1 , P_2 , P_3 , and P_4 .

Recovery from Deadlock: Process Termination

- Abort all deadlocked processes.
- Abort one process at a time until the deadlock cycle is eliminated.
- In which order should we choose to abort?
 - Priority of the process.
 - How long process has computed, and how much longer to completion.
 - Resources the process has used.
 - Resources process needs to complete.
 - How many processes will need to be terminated.
 - Is process interactive or batch?

26

Recovery from Deadlock: Resource Preemption

- Selecting a victim - minimize cost.
- Rollback - return to some safe state, restart process for that state.
- Starvation - same process may always be picked as victim, include number of rollback in cost factor.

27

Deadlock Avoidance

Requires that the system has some additional *a priori* information available.

- Simplest and most useful model requires that each process declare the *maximum number* of resources of each type that it may need.
- The deadlock-avoidance algorithm dynamically examines the resource-allocation state to ensure that there can never be a circular-wait condition.
- Resource-allocation *state* is defined by the number of available and allocated resources, and the maximum demands of the processes.

3

Safe State

- When a process requests an available resource, system must decide if immediate allocation leaves the system in a safe state.
- System is in safe state if there exists a safe sequence of all processes.
- Sequence $\langle P_1, P_2, \dots, P_n \rangle$ is safe if for each P_i , the resources that P_i can still request can be satisfied by currently available resources + resources held by all the P_j , with $j < i$.
 - If P_i resource needs are not immediately available, then P_i can wait until all P_j have finished.
 - When P_j is finished, P_i can obtain needed resources, execute, return allocated resources, and terminate.
 - When P_i terminates, P_{i+1} can obtain its needed resources, and so on.

4

Basic Facts

- If a system is in safe state \Rightarrow no deadlocks.
- If a system is in unsafe state \Rightarrow possibility of deadlock.
- Avoidance \Rightarrow ensure that a system will never enter an unsafe state.

5

Safe, Unsafe, Deadlock State

6

Resource-Allocation Graph Algorithm

- Claim edge $P_i \rightarrow R_j$ indicated that process P_i may request resource R_j ; represented by a dashed line.
- Claim edge converts to request edge when a process requests a resource.
- When a resource is released by a process, assignment edge reconverts to a claim edge.
- Resources must be claimed *a priori* in the system.

7

Resource-Allocation Graph For Deadlock Avoidance

8

Unsafe State In Resource-Allocation Graph

9

Banker's Algorithm

- Multiple instances.
- Each process must a priori claim maximum use.
- When a process requests a resource it may have to wait.
- When a process gets all its resources it must return them in a finite amount of time.

10

Data Structures for the Banker's Algorithm

Let n = number of processes, and m = number of resources types.

- **Available:** Vector of length m . If available $[j] = k$, there are k instances of resource type R_j available.
- **Max:** $n \times m$ matrix. If $Max[i, j] = k$, then process P_i may request at most k instances of resource type R_j .
- **Allocation:** $n \times m$ matrix. If $Allocation[i, j] = k$ then P_i is currently allocated k instances of R_j .
- **Need:** $n \times m$ matrix. If $Need[i, j] = k$, then P_i may need k more instances of R_j to complete its task.

$$Need[i, j] = Max[i, j] - Allocation[i, j].$$

11

Safety Algorithm

1. Let **Work** and **Finish** be vectors of length m and n , respectively. Initialize:
 $Work = Available$
 $Finish[i] = false$ for $i = 1, 3, \dots, n$.
2. Find an i such that both:
 (a) $Finish[i] = false$
 (b) $Need_i \leq Work$
 If no such i exists, go to step 4.
3. $Work = Work + Allocation_i$
 $Finish[i] = true$
 go to step 2.
4. If $Finish[i] == true$ for all i , then the system is in a safe state.

12

Resource-Request Algorithm for Process P_i

Request = request vector for process P_i . If $Request_i[j] = k$ then process P_i wants k instances of resource type R_j .

1. If $Request_i \leq Need_i$ go to step 2. Otherwise, raise error condition, since process has exceeded its maximum claim.
2. If $Request_i \leq Available$, go to step 3. Otherwise P_i must wait, since resources are not available.
3. Pretend to allocate requested resources to P_i by modifying the state as follows:

$$\begin{aligned} Available &= Available - Request_i; \\ Allocation_i &= Allocation_i + Request_i; \\ Need_i &= Need_i - Request_i; \end{aligned}$$

- If safe \Rightarrow the resources are allocated to P_i .
- If unsafe $\Rightarrow P_i$ must wait, and the old resource-allocation state is restored

13

Example of Banker's Algorithm

- 5 processes P_0 through P_4 ; 3 resource types A (10 instances), B (5 instances), and C (7 instances).
- Snapshot at time T_0 :

| | <u>Allocation</u> | <u>Max</u> | <u>Available</u> |
|-------|-------------------|--------------|------------------|
| | <i>A B C</i> | <i>A B C</i> | <i>A B C</i> |
| P_0 | 0 1 0 | 7 5 3 | 3 3 2 |
| P_1 | 2 0 0 | 3 2 2 | |
| P_2 | 3 0 2 | 9 0 2 | |
| P_3 | 2 1 1 | 2 2 2 | |
| P_4 | 0 0 2 | 4 3 3 | |

14

Example (Cont.)

- The content of the matrix. Need is defined to be $Max - Allocation$.

| | <u>Need</u> |
|-------|--------------|
| | <i>A B C</i> |
| P_0 | 7 4 3 |
| P_1 | 1 2 2 |
| P_2 | 6 0 0 |
| P_3 | 0 1 1 |
| P_4 | 4 3 1 |

15

Example P_1 Request (1,0,2) (Cont.)

- Check that Request \leq Available (that is, (1,0,2) \leq (3,3,2) \Rightarrow true.

| | <u>Allocation</u> | <u>Need</u> | <u>Available</u> |
|-------|-------------------|-------------|------------------|
| | A B C | A B C | A B C |
| P_0 | 0 1 0 | 7 4 3 | 2 3 0 |
| P_1 | 3 0 2 | 0 2 0 | |
| P_2 | 3 0 1 | 6 0 0 | |
| P_3 | 2 1 1 | 0 1 1 | |
| P_4 | 0 0 2 | 4 3 1 | |

- Executing safety algorithm shows that sequence $\langle P_1, P_3, P_4, P_0, P_2 \rangle$ satisfies safety requirement.
- Can request for (3,3,0) by P_4 be granted?
- Can request for (0,2,0) by P_0 be granted?
