#### CSC 4103 - Operating Systems Fall 2009

LECTURE - XII

DEADLOCKS - III

Tevfik Koşar

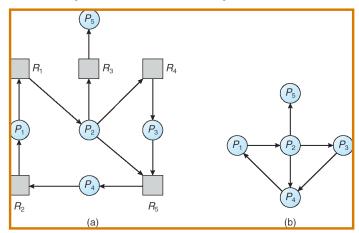

Louisiana State University October 6<sup>th</sup>, 2009

### **Deadlock Detection**

- Allow system to enter deadlock state
- Detection algorithm
- Recovery scheme

# Single Instance of Each Resource Type

- Maintain wait-for graph
  - Nodes are processes.
  - $P_i \rightarrow P_j$  if  $P_i$  is waiting for  $P_j$ .

Resource-Allocation Graph

Corresponding wait-for graph

3

## Single Instance of Each Resource Type

- Periodically invoke an algorithm that searches for a cycle in the graph.
- An algorithm to detect a cycle in a graph requires an order of  $n^2$  operations, where n is the number of vertices in the graph.
- Only good for single-instance resource allocation systems.

### Several Instances of a Resource Type

- Available: A vector of length m indicates the number of available resources of each type.
- Allocation: An n x m matrix defines the number of resources of each type currently allocated to each process.
- Request: An  $n \times m$  matrix indicates the current request of each process. If Request  $[i_j] = k$ , then process  $P_i$  is requesting k more instances of resource type.  $R_i$ .

5

## **Detection Algorithm**

- 1. Let *Work* and *Finish* be vectors of length *m* and *n*, respectively Initialize:
  - (a) Work = Available
  - (b) For i = 0,2, ..., n-1, if  $Allocation_i \neq 0$ , then Finish[i] = false; otherwise, <math>Finish[i] = true.
- 2. Find an index *i* such that both:
  - (a) Finish[i] == false
  - (b)  $Request_i \leq Work$

If no such *i* exists, go to step 4.

### Detection Algorithm (Cont.)

- 3. Work = Work + Allocation; Finish[i] = true go to step 2.
- 4. If Finish[i] == false, for some i,  $0 \le i \le n-1$ , then the system is in deadlock state. Moreover, if Finish[i] == false, then  $P_i$  is deadlocked.

Algorithm requires an order of  $O(m \times n^2)$  operations to detect whether the system is in deadlocked state.

7

### **Example of Detection Algorithm**

- Five processes  $P_0$  through  $P_4$ ; three resource types A (7 instances), B (2 instances), and C (6 instances).
- Snapshot at time  $T_0$ :

#### AllocationRequest Available

$$ABC$$
  $ABC$   $ABC$   $ABC$ 
 $P_0$  010 000 000
 $P_1$  200 202
 $P_2$  303 000
 $P_3$  211 100
 $P_4$  002 002

• Sequence  $\langle P_0, P_2, P_3, P_1, P_4 \rangle$  will result in *Finish*[*i*] = true for all *i*.

8

## Example (Cont.)

•  $P_2$  requests an additional instance of type C.

#### Request

ABC

 $P_0 \ 0 \ 0 \ 0$ 

 $P_1$  201

 $P_2 = 0.01$ 

 $P_3$  100

 $P_4 002$ 

- State of system?
  - Can reclaim resources held by process  $P_0$ , but insufficient resources to fulfill other processes; requests.
  - Deadlock exists, consisting of processes  $P_1$ ,  $P_2$ ,  $P_3$ , and  $P_{4\cdot_{q}}$

#### Recovery from Deadlock: Process Termination

- Abort all deadlocked processes.
- Abort one process at a time until the deadlock cycle is eliminated.
- In which order should we choose to abort?
  - Priority of the process.
  - How long process has computed, and how much longer to completion.
  - Resources the process has used.
  - Resources process needs to complete.
  - How many processes will need to be terminated.
  - Is process interactive or batch?

#### Recovery from Deadlock: Resource Preemption

- Selecting a victim minimize cost.
- Rollback return to some safe state, restart process for that state.
- Starvation same process may always be picked as victim, include number of rollback in cost factor.

27

#### **Deadlock Avoidance**

Requires that the system has some additional *a priori* information available.

- Simplest and most useful model requires that each process declare the *maximum number* of resources of each type that it may need.
- The deadlock-avoidance algorithm dynamically examines the resource-allocation state to ensure that there can never be a circular-wait condition.
- Resource-allocation *state* is defined by the number of available and allocated resources, and the maximum demands of the processes.

#### Safe State

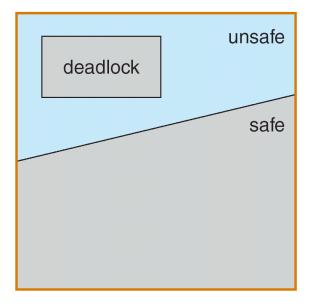

- When a process requests an available resource, system must decide if immediate allocation leaves the system in a safe state.
- System is in safe state if there exists a safe sequence of all processes.
- Sequence <P<sub>1</sub>, P<sub>2</sub>, ..., P<sub>n</sub>> is safe if for each P<sub>i</sub>, the resources that P<sub>i</sub> can still request can be satisfied by currently available resources + resources held by all the P<sub>i</sub>, with j<I.</li>
  - If  $P_i$  resource needs are not immediately available, then  $P_i$  can wait until all  $P_i$  have finished.
  - When  $P_j$  is finished,  $P_i$  can obtain needed resources, execute, return allocated resources, and terminate.
  - When  $P_i$  terminates,  $P_{i+1}$  can obtain its needed resources, and so on.

/

#### **Basic Facts**

- If a system is in safe state ⇒ no deadlocks.
- If a system is in unsafe state ⇒ possibility of deadlock.
- Avoidance ⇒ ensure that a system will never enter an unsafe state.

### Safe, Unsafe, Deadlock State

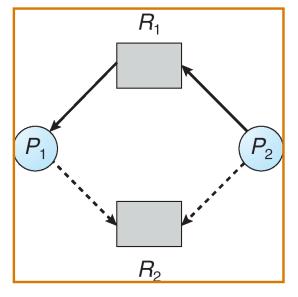

6

## Resource-Allocation Graph Algorithm

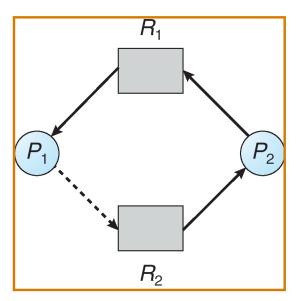

- Claim edge  $P_i \rightarrow R_j$  indicated that process  $P_j$  may request resource  $R_j$ ; represented by a dashed line.
- Claim edge converts to request edge when a process requests a resource.
- When a resource is released by a process, assignment edge reconverts to a claim edge.
- Resources must be claimed a priori in the system.

## Resource-Allocation Graph For Deadlock Avoidance

8

# Unsafe State In Resource-Allocation Graph

9

### Banker's Algorithm

- Multiple instances.
- Each process must a priori claim maximum use.
- When a process requests a resource it may have to wait.
- When a process gets all its resources it must return them in a finite amount of time.

10

#### Data Structures for the Banker's Algorithm

Let n = number of processes, and m = number of resources types.

- Available: Vector of length m. If available [j] = k, there are k instances of resource type  $R_j$  available.
- Max:  $n \times m$  matrix. If Max [i,j] = k, then process  $P_i$  may request at most k instances of resource type  $R_i$ .
- Allocation:  $n \times m$  matrix. If Allocation[i,j] = k then  $P_i$  is currently allocated k instances of  $R_i$ .
- Need:  $n \times m$  matrix. If Need[i,j] = k, then  $P_i$  may need k more instances of  $R_j$  to complete its task.

Need [i,j] = Max[i,j] - Allocation [i,j].

11

### Safety Algorithm

1. Let *Work* and *Finish* be vectors of length *m* and *n*, respectively. Initialize:

Work = Available Finish [i] = false for i - 1,3, ..., n.

- 2. Find an *i* such that both:
  - (a) Finish [i] = false
  - (b)  $Need_i \leq Work$

If no such *i* exists, go to step 4.

- 3. Work = Work + Allocation; Finish[i] = true go to step 2.
- 4. If *Finish* [*i*] == true for all *i*, then the system is in a safe state.

12

### Resource-Request Algorithm for Process $P_i$

Request = request vector for process  $P_i$ . If  $Request_i[j] = k$  then process  $P_i$  wants k instances of resource type  $R_{j}$ .

- 1. If *Request*<sub>i</sub> ≤ *Need*<sub>i</sub> go to step 2. Otherwise, raise error condition, since process has exceeded its maximum claim.
- 2. If  $Request_i \leq Available$ , go to step 3. Otherwise  $P_i$  must wait, since resources are not available.
- 3. Pretend to allocate requested resources to  $P_i$  by modifying the state as follows:

Available = Available - Request;; Allocation; = Allocation; + Request;; Need; = Need; - Request;;

- If safe  $\Rightarrow$  the resources are allocated to Pi.
- If unsafe ⇒ Pi must wait, and the old resourceallocation state is restored

## Example of Banker's Algorithm

- 5 processes P<sub>0</sub> through P<sub>4</sub>; 3 resource types A
   (10 instances),
   B (5instances, and C (7 instances).
- Snapshot at time  $T_0$ :

	<u>Allocation</u>	<u>Max</u>	<u>Available</u>
	ABC	ABC	ABC
$P_0$	0 1 0	753	3 3 2
P	200	3 2 2	
Р	302	902	
Р	3 211	2 2 2	
P	4 002	433	

14

## Example (Cont.)

• The content of the matrix. Need is defined to be Max - Allocation.

### Example $P_1$ Request (1,0,2) (Cont.)

• Check that Request  $\leq$  Available (that is,  $(1,0,2) \leq (3,3,2) \Rightarrow$  true.

<u>Allocation</u>		<u>Need</u>	<u>Available</u>
	ABC	ABC	ABC
$P_0$	0 1 0	7 4 3	2 3 0
$P_1$	3 0 2	020	
$P_2$	3 0 1	600	
$P_3$	2 1 1	0 1 1	
$P_4$	002	4 3 1	

- Executing safety algorithm shows that sequence <P1, P3, P4, P0, P2> satisfies safety requirement.
- Can request for (3,3,0) by P4 be granted?
- Can request for (0,2,0) by P0 be granted?
